Chapter 1

Introduction

1.1 Motivation

The medical discipline of pathology is in a digital transformation. Instead of looking at tissue samples through the means of traditional light microscopy, it is now possible to digitize those samples. This digitalization is done with the help of a so called slide scanner. The result of such an operation is a *whole slide image* (WSI) [9]. The digital nature of WSIs opens the door to the realm of image processesing and analysis which yields certain benefits, such as the use of image segmentation and registration methods to support the pathologist in his/her work.

A very promising approach to image analysis is the use of *neural networks*¹. These are a group of computational models inspired by our current understanding of biological NN. The construct of many interconnected neurons is considered a NN (both in the biological and artificial context). Each single one of those neurons has input values and an output value. Once the input reaches a certain trigger point, the cell in the neuron sends a signal as output. The connections between the neurons are weighted and can dampen or strengthen a signal. Because of this, old pathways can be blocked and new ones created. In other words, a NN is capable of "learning" [46]. This is a huge advantage compared to other software models. While certain problems are "easier" to solve in a sequential, algorithmic fashion (say an equation or the towers of hanoi), certain problems (e.g. image segmentation or object recognition) are very complex, so that new approaches are needed, while other problems can't be solved algorithmically at all. With the use of adequate training samples, a NN can learn to solve a problem, much like a human.

In the recent past the use of NN enabled major breakthroughs, especially in the area of image classification and object recognition. Karpathy and Fei-Fei, for example, created a NN that is capable of describing an image or a scene using natural language text blocks [1] (see fig. 1.1 for a selection of examples).

¹See chapter 2.2

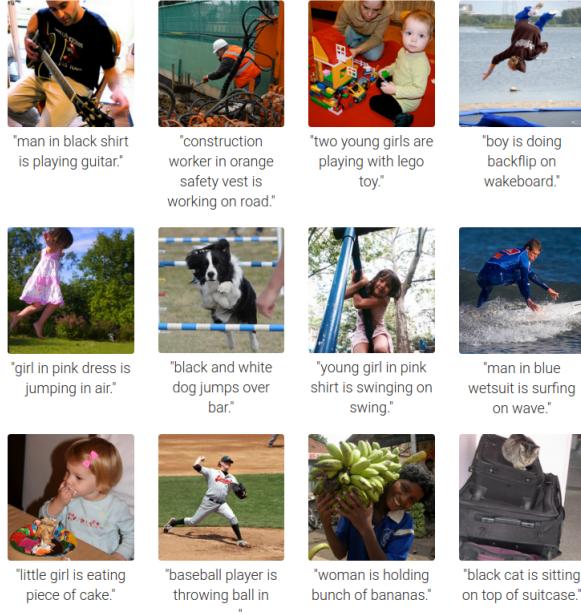

Figure 1.1: Example results of the in [1] introduced model (source: <http://cs.stanford.edu/people/karpathy/deepimagesent/>)

There is enormous potential in the use of NN in the digital pathology as well, but to transfer these models and technologies, certain obstacles must be overcome. One of those is the need for proper training samples. While generally there are large amounts of WSIs (e.g. publicly available at the Cancer Genome Atlas²), most of them won't be usable as a training sample without further preparation.

A possible way to prepare them is by using image annotation: tagging regions of interest (ROI) on an image and assigning labels or keywords as metadata to those tags. These can be added to the WSIs, stored and later used for training. The result of such an approach could be similar to the one of Karpathy and Fei-Fei [1], but with a medical context instead of daily situations.

Therefore the goal of this thesis is to provide tools for pathologists and data scientists to annotate WSIs and save those annotations in such a way that they will be usable later in combination with NN.

1.2 Research Objective

The objective of this thesis is the conceptualization and implementation of tools to prepare WSIs for the further use as training samples in NN. To achieve this,

²<https://gdc-portal.nci.nih.gov/>

a process chain with all the necessary steps needs to be established. The chain consists of the following tasks:

- (A) open WSI with a viewer tool
- (B) annotate opened WSI
- (C) extract annotations and prepare them for the use as training sample in a NN

There is no standardized WSI file format [9]. Hence, slide scanner vendors developed their own proprietary solutions. This either leads to

- (i) locking-in on a specific vendor or
 - (ii) separate handling of each proprietary format
- (i) would render the whole process chain vendor specific, limiting its use drastically. (ii) would not render the process chain vendor specific but call for a lot of additional work and maintenance, due to the separate handling of different formats. To counteract this, open file formats have been specified [9]:

- JPEG2000
- TIFF
- Deep Zoom Images (DZI)
- DICOM (supplement 145), without reference implementation as of yet [9]

Therefore, to achieve (A), the first step of the process chain is to establish a tool with which WSIs of various vendor specific formats can be turned into an open file format. This way, neither (i) nor (ii) will arise as a problem.

To achieve (A) and (B), it is also necessary to deploy a graphical user interface (GUI), that not only makes it possible to open and view a WSI (A), but also enables the user to annotate the WSI, as well as manage made annotations (B).

To achieve (C), another tool needs to be established, that is capable of turning saved annotations into training samples which are prepared for a further use in NN.

In summary: to reach the research objective of this thesis, tools to achieve the following tasks need to be established:

- (a) conversion of various WSI formats into an open format
- (b) annotation of WSIs and management thereof
- (c) extracting and preparing annotations as training samples for later use in NN

1.3 About this thesis

This thesis contains 6 chapters.

Chapter 1 - Introduction and *2 - Background* address the scope, background and vocabulary of this thesis.

The chapters 3 to 5 address the components described in the last section: *chapter 3 - Conversion Service* will describe a tool for image conversion, *chapter 4 - Annotation Service* will describe a tool for image annotation and *chapter 5 - Tessellation Service* will describe an extraction tool, to prepare the annotations made with the Annotation Service for the use in a NN.

Finally, *Chapter 6 - Conclusion* will discuss and conclude the findings of the aforementioned chapters.

Chapter 2

Background

2.1 Whole Slide Image Formats

Due to the amount of data stored in a raw, uncompressed WSI¹, file formatting and compression are required to make working with WSIs feasible. Since there is no standardized format for WSIs, vendors came up with their own, proprietary solutions, which vary greatly [9]. Efforts of standardization are being made through the *Digital Imaging and Communications in Medicine* (DICOM) Standard [14].

Usually, WSI files are stored as a multitude of single images, spanning multiple folders and different resolutions. Those files are used to construct a so called *image pyramid* [26] (see fig. 2.1 and subsection 2.1.1).

2.1.1 DICOM Supplement 145

Singh et al. [27] describe DICOM as follows:

"Digital Imaging and Communications in Medicine (DICOM), synonymous with ISO (International Organization for Standardization) standard 12052, is the global standard for medical imaging and is used in all electronic medical record systems that include imaging as part of the patient record."

Before *Supplement 145: Whole Slide Microscopic Image IOD and SOP Classes*, the DICOM Standard did not address standardization of WSI. Among others, the College of American Pathologist's Diagnostic Intelligence and Health Information Technology Committee is responsible for the creation and further advancement of this supplement [27].

It addresses every step involved in creating WSIs: image creation, acquisition, processing, analyzing, distribution, visualization and data management

¹ A typical 1,600 megapixel slide requires about 4.6 GB of memory on average [26]. The size of a H&E (hematoxylin and eosin) stained slide ranges typically from 4 to 20 GB [27].

[14]. It impacted the way how data is stored greatly [27], due to the introduction of a pyramid image model [14] (see fig. 2.1).

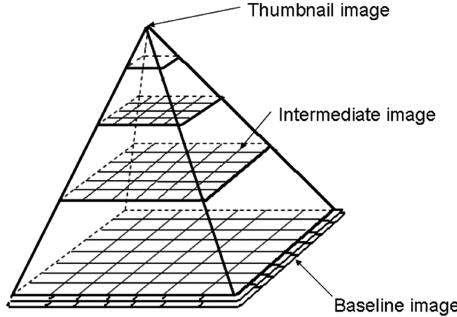

Figure 2.1: DICOMs image pyramid (source: [27])

The image pyramid model facilitates rapid zooming and reduces the computational burden of randomly accessing and traversing a WSI [27], [28]. This is made possible by storing an image in several precomputed resolutions, with the highest resolution sitting at the bottom (called the *baseline image*) and a thumbnail or low power image at the top (compare fig. 2.1) [14]. This creates a pyramid like stack of images, hence the name "pyramid model". The different resolutions are referred to as *layers* [14] or *levels* [27] respectively.

Each level is tessellated into square or rectangular fragments, called tiles, and stored in a two dimensional array [26].

Because of this internal organization, the tiles of each level can be retrieved and put together separately, to either form a subregion of the image or show it entirely. This makes it easy to randomly access any subregion of the image without loading large amounts of data [27].

2.1.2 Proprietary Formats

Vendors of whole slide scanners implement their own file formats, libraries and viewers (see tab. 2.1 for a list of vendors and their formats). Because of this, they can focus on the key features and abilities of their product. This generally leads to a higher usability, ease-of-use and enables highly tailored customer support. Furthermore, in comparison to open source projects, the longevity of proprietary software is often higher [39].

vendor	formats
Aperio	SVS, TIF
Hamamatsu	VMS, VMU, NDPI
Leica	SCN
3DHistech/Mirax	MRXS
Philips	TIFF
Sakura	SVSLIDE
Trestle	TIF
Ventana	BIF, TIF

Table 2.1: File formats by vendor

Since the proprietary formats have little to no documentation, most of the subsequently presented information was reverse engineered in [19] and [53]. All proprietary formats listed here implement a modified version of the pyramid model introduced in 2.1.1

Aperio

The SVS format by Aperio is a TIFF-based format, which comes in a single file [19]. It has a specific internal organization in which the first image is the baseline image, which is always tiled (usually with 240x240 pixels). This is followed by a thumbnail, typically with dimensions of about 1024x768 pixels. The thumbnail is followed by at least one intermediate pyramid image (compare fig. 2.1), with the same compression and tile organization as the baseline image [53]. Optionally, there may be a slide label and macro camera image at the end of each file [53].

Hamamatsu

Hamamatsu WSIs come in 3 variants:

- (1) VMS
- (2) VMU
- (3) NDPI

(1) and (2) consist of an index file ((1) - [file name].vms, (2) - [file name].vmu) and 2 or more image files. In the case of (2), there is also an additional optimization file. (3) consists of a single TIFF-like file with custom TIFF tags. While (1) and (3) contain JPEG images, (2) contains a custom, uncompressed image format called *NGR*² [53].

The random access support for decoding parts of jpeg files is poor [53]. To get around this, so called *restart markers*³ are used to create virtual slides [19]. The

²For more information on NGR, consult <http://openslide.org/formats/hamamatsu/>

³Restart markers were originally designed for error recovery. The markers allow the decoder to resynchronize at set intervals throughout the image [19].

markers are placed at regular intervals. The offset of every marker is specified in different manner. In the case of (1), it can be found in the index file. In the case of (2), the optimization file holds the information and in the case of (3), a TIFF tag contains the offset [53].

Leica

SCN is a single file format based on BigTIFF that additionally provides a pyramidal thumbnail image [19]. The first TIFF directory has a tag called "ImageDescription" which contains an XML document that defines the internal structure of the WSI [53].

Leica WSIs are structured as a collection of images, each of which has multiple pyramid levels. While the collection only has a size, images have a size and position, all measured in nanometers. Each dimension has a size in pixels, an optional focal plane number, and a TIFF directory containing the image data. Fluorescence images have different dimensions (and thus different TIFF directories) for each channel [53].

Brightfield slides have at least two images: a low-resolution macro image and one or more main images corresponding to regions of the macro image. Fluorescence slides can have two macro images: one brightfield and one fluorescence [53].

3DHistech/Mirax

MRXS is a multi-file format with complex metadata in a mixture of text and binary formats. Images are stored as either JPEG, PNG or BMP [19]. The poor handling of random access is also applicable to PNG. Because of this, multiple images are needed to encode a single slide image. To avoid having many individual files, images are packed into a small number of data files. An index file provides offsets into the data files for each required piece of data. [53].

A 3DHistech/Mirax scanner take images with an overlap. Each picture taken is then tessellated without an overlap. Therefore, overlap only occurs between taken pictures [53].

The generation of the image pyramid differs from the process described in 2.1.1 To create the n^{th} level, each image of the $n^{th} - 1$ level is divided by 2 in each dimension and then concatenated into a new image. Where the $n^{th} - 1$ level had 4 images in 2x2 neighborhood, the n^{th} level will only have 1 image. This process has no regards for overlaps. Thus, overlaps may occur in the higher levels of the image pyramid [53].

Philips

Philips' TIFF is an export from the native iSyntax format. An XML document with the hierarchical structure of the WSI can be found over the *ImageDescription* tag of the first TIFF directory. It contains key-value pairs based on DICOM tags [53].

Slides with multiple regions of interest are structured as a single image pyramid enclosing all regions. Slides may omit pixel data for TIFF tiles not in an ROI. When such tiles are downsampled into a tile that does contain pixel data, their contents are rendered as white pixels [53].

Label and macro images are stored either as JPEG or as stripped TIFF directories.

Sakura

WSIs in the SVSLIDE format are SQLite 3 database files. Their tables contain the metadata, associated images and tiles in the JPEG format. The tiles are addressed as a tuple of (focal plane, downsample, level-0 X coordinate, level-0 Y coordinate, color channel). Additionally, each color channel has a separate grayscale image [53].

Trestle

Trestles TIF is a single-file TIFF. The WSI has the standard pyramidal scheme and tessellation. It contains non-standard metadata and overlaps, which are specified in additional files. The first image in the TIFF file is the baseline image. Subsequent images are assumed to be consecutive levels of the image pyramid with decreasing resolution [53].

Ventana

Ventanas WSIs are single-file BigTIFF images, organized in the typical pyramidal scheme. The images are tiled and have non-standard metadata, as well as overlaps. They come with a macro and a thumbnail image [53].

2.1.3 Open Formats

As mentioned in 2.1.2, proprietary formats typically come without much or any documentation. Furthermore, a vendor's viewer is usually the only way of viewing WSIs of a particular format. This creates a vendor lock-in, where users can't take advantage of new improvements offered by other vendors. Furthermore, most viewers only provide support for Windows platforms. While, in a clinical setting, Windows may dominate the market, a significant amount of users in medical research prefer Linux or Mac OS X [19]. The use of mobile platforms, such as iOS or Android tablets may also have a great influence of the work flow in the future. Some vendors try to compensate for this fact with a server-based approach, which hurts performance by adding a network round-trip delay on every digital slide operation [19].

To resolve these issues, open image formats have been suggested, which will be discussed further in the following subsections.

Deep Zoom Images

The Deep Zoom Image (DZI) format is an XML-based file format, developed and maintained by Microsoft [50]. A DZI is a pyramidal, tiled image (see fig. 2.2), similar to the one described in 2.1.1 (compare 2.1 and 2.2), with two exceptions:

1. the baseline image is referred to as the highest level, instead of the lowest; this either turns the image pyramid or its labeling upside down
2. tiles are always square, with the exception of the last column/row

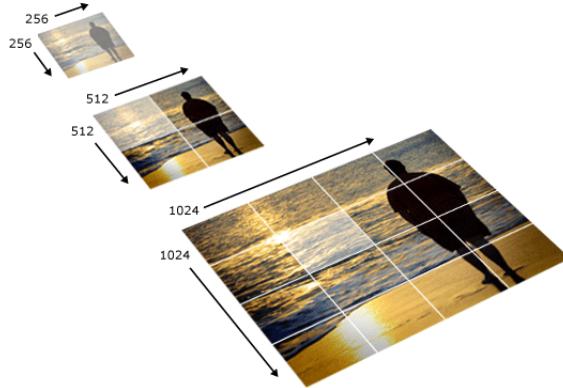

Figure 2.2: DZI pyramid model example (source: [50])

A DZI consists of two main parts [50]:

- (1) a describing XML file ([file name].dzi) with the following metadata:
 - format of individual tiles (e.g. JPEG or PNG)
 - overlap between tiles
 - size of individual tiles
 - height and width of baseline image
- (2) a directory ([file name]_files) containing image tiles of the specified format
 - (1) and (2) are stored "next" to each other, so that there are 2 separate files. (2) contains sub directories, one for each level of the image pyramid. The baseline image of a DZI is in the highest level. Each level is tessellated into as many tiles necessary to go over the whole image, with each tile having the size specified in the XML file. If the image size is no multiple of the specified tile size, the width of the n^{th} column of tiles will be $(width \bmod tile\ size)$ pixels. Equally, the height of the m^{th} row will be $(height \bmod tile\ size)$ pixels. Thus, the outermost right bottom tile $t_{n,m}$ will be of $(width \bmod tile\ size) \times (height \bmod tile\ size)$ pixels.

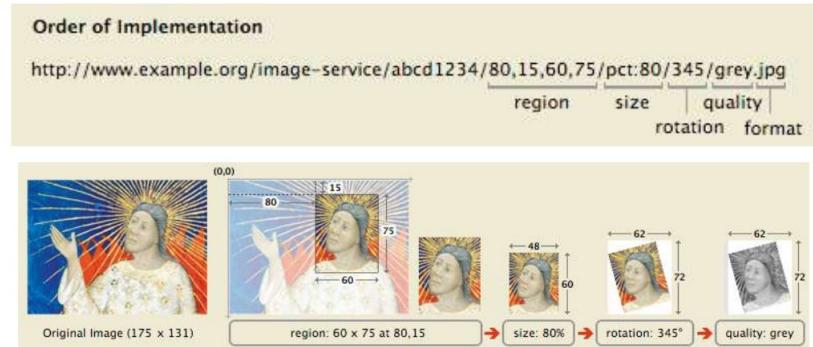

International Image Interoperability Framework

The International Image Interoperability Framework (IIIF) is the result of a cooperation between The British Library, Stanford University, the Bodleian Libraries⁴, the Bibliothèque Nationale de France, Nasjonalbiblioteket⁵], Los Alamos National Laboratory Research Library and Cornell University [10]. Version 1.0 was published in 2012.

IIIF's goal is to collaboratively produce an interoperable technology and community framework for image delivery [37]. To achieve this, IIIF tries to:

- (1) give scholars access to image-based resources around the world
- (2) define a set of common APIs to support interoperability between image repositories
- (3) develop and document shared technologies (such as image servers and web clients), that enable scholars to view, compare, manipulate and annotate images

IIIF Image Delivery API

<http://library.stanford.edu/iiif/image-api>

Figure 2.3: Example of iiif request (source:<http://www.slideshare.net/Tom-Cramer/iiif-international-image-interoperability-framework-dlf2012?ref=https://www.diglib.org/forums/2012forum/transcending-silos-leveraging-linked-data-and-open-image-apis-for-collaborative-access-to-digital-facsimiles/>)

⁴Oxford University

⁵National Library of Norway

The part relevant for this thesis is (2), especially the image API [24]. It specifies a web service that returns an image in response to a standard web request. The URL can specify the region, size, rotation, quality and format of the requested image (see 2.3). Originally intended for resources in digital image repositories maintained by cultural heritage organizations, the API can be used to retrieve static images in response to a properly constructed URL [36]. The URL scheme looks like this⁶:

```
1 {scheme}://{server}/{prefix}/{identifier}/{region}/{size}/{rotation}
   }/{quality}.{format}
```

The *region* and *size* parameters are of special interest for this thesis. With them, it is possible to request only a certain region of an image in a specified size.

The *region* parameter defines the rectangular portion of the full image to be returned. It can be specified by pixel coordinates, percentage or by the value “full” (see tab. 2.2 and fig. 2.4).

Form	Description
full	The complete image is returned, without any cropping.
x,y,w,h	The region of the full image to be returned is defined in terms of absolute pixel values. The value of x represents the number of pixels from the 0 position on the horizontal axis. The value of y represents the number of pixels from the 0 position on the vertical axis. Thus the x,y position 0,0 is the upper left-most pixel of the image. w represents the width of the region and h represents the height of the region in pixels.
pct:x,y,w,h	The region to be returned is specified as a sequence of percentages of the full image’s dimensions, as reported in the Image Information document. Thus, x represents the number of pixels from the 0 position on the horizontal axis, calculated as a percentage of the reported width. w represents the width of the region, also calculated as a percentage of the reported width. The same applies to y and h respectively. These may be floating point numbers.

Table 2.2: Valid values for *region* parameter (source: [24])

If the request specifies a region whose size extends beyond the actual size of the image, the response should be a cropped image, instead of an image with added empty space. If the region is completely outside of the image, the response should be a ”404 Not Found” http status code [24].

⁶For detailed information on all parameters see the official API: <http://iiif.io/api/image/2.0>

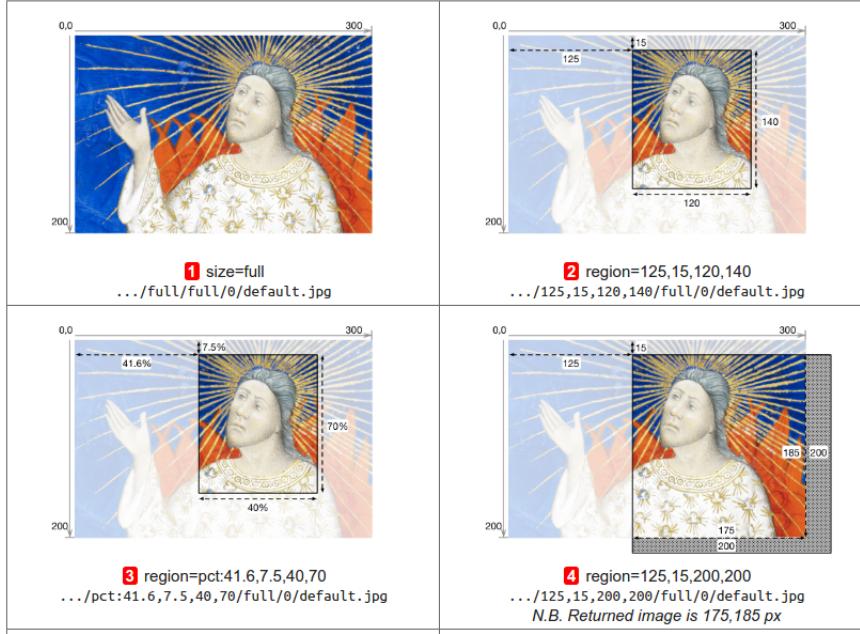

Figure 2.4: Results of IIIF request with different values for region parameter (source: [24])

If a region was extracted, it is scaled to the dimensions specified by the size parameter (see tab. 2.3 and fig. 2.5).

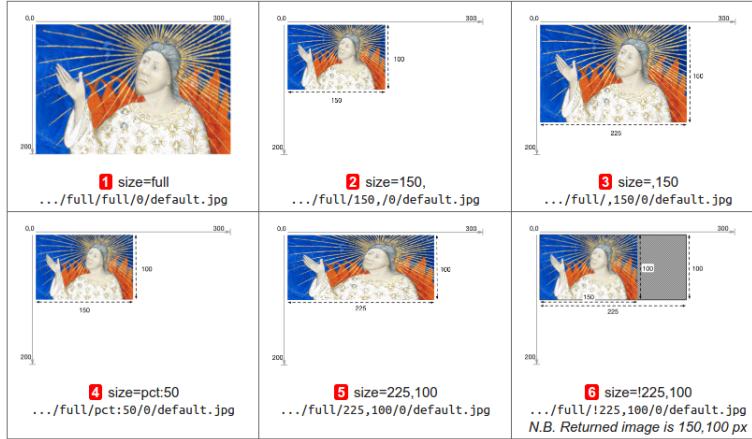

Figure 2.5: Results of IIIF request with different values for size parameter (source: [24])

If the resulting height or width equals 0, then the server should return a "400 Bad Request" http status code. Depending on the image server, scaling above the full size of the extracted region may be supported [24].

Form	Description
full	The extracted region is not scaled, and is returned at its full size.
w,	The extracted region should be scaled so that its width is exactly equal to w, and the height will be a calculated value that maintains the aspect ratio of the extracted region.
,h	The extracted region should be scaled so that its height is exactly equal to h, and the width will be a calculated value that maintains the aspect ratio of the extracted region.
pct:n	The width and height of the returned image is scaled to n% of the width and height of the extracted region. The aspect ratio of the returned image is the same as that of the extracted region.
w,h	The width and height of the returned image are exactly w and h. The aspect ratio of the returned image may be different than the extracted region, resulting in a distorted image.
!w,h	The image content is scaled for the best fit such that the resulting width and height are less than or equal to the requested width and height. The exact scaling may be determined by the service provider, based on characteristics including image quality and system performance. The dimensions of the returned image content are calculated to maintain the aspect ratio of the extracted region.

Table 2.3: Valid values for *size* parameter (source: [24])

To use the IIIF API, a compliant web server must be deployed. Loris and IIPIImageserver are examples for open source IIIF API compliant systems [36]:

- **Loris**, an open source image server based on python that supports the IIIF API versions 2.0, 1.1 and 1.0. Supported image formats are JPEG, JPEG2000 and TIFF.
- **IIPIImage Server**, an open source Fast CGI module written in C++, that is designed to be embedded within a hosting web server such as Apache, Lighttpd, MyServer or Nginx. Supported image formats are JPEG2000 and TIFF [37].

OpenStreetMap/Tiled Map Service

OpenStreetMap (OSM) is a popular tile source used in many online geographic mapping specifications [36]. It's a community driven alternative to services such as Google Maps. Information is added by users via aerial images, GPS devices and field maps. All OSM data is classified as *open data*, meaning that it can be used anywhere, as long as the OSM Foundation is credited [33].

Tiled Map Service (TMS) is a tile scheme developed by the Open Source Geospatial Foundation (OSGF) [36] and specified in [32]. The OSGF is a non-profit organization whose goal it is to support the needs of the open source geospatial community. TMS provides access to cartographic maps of geo-referenced data. Access to these resources is provided via a "REST" interface, starting with a root resource describing available layers, then map resources with a set of scales, then scales holding sets of tiles [32].

Both, OSM and TMS, offer zooming images, which in general, have the functionality necessary, to be of use for this thesis. Unfortunately, they are also highly specialized on the needs of the mapping community, with many features not needed in the context of this thesis.

JPEG 2000

[45] describes the image compression standard JPEG 2000 as follows:

"JPEG 2000 is an image coding system that uses state-of-the-art compression techniques based on wavelet technology. Its architecture lends itself to a wide range of uses from portable digital cameras through to advanced pre-press, medical imaging and other key sectors."

It incorporates a mathematically lossless compression mode, in which the storage requirement of images can be reduced by an average of 2:1. On top of that, there is a visually lossless compression mode⁷ with compression rates between 10:1 to 20:1 [40]. JPEG 2000 code streams offer mechanisms to support random access at varying degrees of granularity. It is possible to store different parts of the same picture using different quality [13].

In the compression process, JPEG 2000 partitions an image into rectangular and non-overlapping tiles of equal size (except for tiles at the image borders). The tile size is arbitrary and can be as large as the original image itself (resulting in only one tile) or as small as a single pixel. Furthermore, the image gets decomposed into a multiple resolution representation [48].

This creates a tiled image pyramid, similar to the one described in subsection 2.1.1.

The encoding-decoding process of JPEG 2000 is beyond the scope of this thesis. Therefore, it is recommended to consult either [40] for a quick overview or [48] for an in depth guide.

⁷At visually lossless compression rates, even a trained observer can't see the difference between original and compressed version [40].

TIFF/BigTIFF

The Tagged Image File Format (TIFF) consists of a number of corresponding key-value pairs (e.g. *ImageWidth* and *ImageLength*, who describe the width and length of the contained image) called *tags*. One of the core features of this format is that it allows for the image data to be stored in tiles [18].

Each tile offset is saved in an image header, so that efficient random access to any tile is granted. The original specification demands a use of 32 bit file offset values, limiting the maximum offset to 2^{32} . This constraint limits the file size to be below 4 GB [18].

This constraint led to the development of BigTIFF. The offset values were raised to a 64 bit base, limiting the maximum offset to 2^{64} . This results in an image size of up to 18,000 peta bytes [15].

TIFF and BigTIFF are capable of saving images in multiple resolutions. Together with the feature of saving tiles, the image pyramid model (as described in subsection 2.1.1) can be applied [16].

2.2 Short Introduction to Neural Networks

The objective of the workflows introduced in chapter 1.2 is to create training samples for NNs. Before going into other details, it is necessary to clarify what NNs are, how they work, why they need training samples and what they are used for⁸.

Artificial NNs are a group of models inspired by Biological Neural Networks (BNN) . BNNs can be described as an interconnected web of neurons (see 2.6), whose purpose it is to transmit information in the form of electrical signals. A neuron receives input via dendrites and sends output via axons [57]. An average human adult brain contains about 10^{11} neurons. Each of those receives input from about 10^4 other neurons. If their combined input is strong enough, the receiving neuron will send an output signal to other neurons [12].

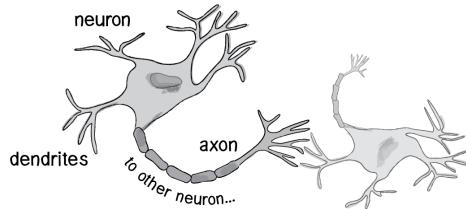

Figure 2.6: Neuron in a BNN (source: [57])

⁸ An in-depth introduction into the field of NNs is far beyond the scope of this work. For further information about NNs, consultation of literature (e.g. [8], [12], [25], [46], [57]) is highly recommended.

Although artificial NNs are much simpler in comparison⁹, they generally work in the same fashion.

One of the biggest strengths of a NN, much like a BNN, is the ability to adapt by learning¹⁰. This adaption is based on *weights* that are assigned to the connections between single neurons. Fig 2.7 shows an exemplary NN with neurons and the connections between them.

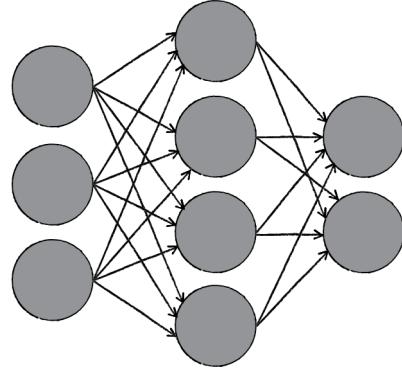

Figure 2.7: Exemplary NN (source: [57])

Each line in fig. 2.7 represents a connection between 2 neurons. Those connections are a one-directional flow of information, each assigned with a specific weight. This weight is a simple number that is multiplied with the incoming/outgoing signal and therefore weakens or enhances it. They are the defining factor of the behavior of a NN. Determining those values is the purpose of training a NN [12].

According to [57], some of the standard use cases for NN are:

- Pattern Recognition
- Time Series Prediction
- Signal Processing Perceptron
- Control
- Soft Sensors
- Anomaly Detection

2.2.1 Methods of Learning

There are 3 general strategies when it comes to the training of a NN [12]. Those are:

⁹Usually, they don't have much more than a few dozen neurons [12].

¹⁰As humans, NN learn by training [57].

1. Supervised Learning
2. Unsupervised Learning
3. Reinforcement Learning (a variant of Unsupervised Learning [55])

Supervised Learning is a strategy that involves a training set to which the correct output is known, as well as an observing teacher. The NN is provided with the training data and computes its output. This output is compared to the expected output and the difference is measured. According to the error made, the weights of the NN are corrected. The magnitude of the correction is determined by the used learning algorithm [55].

Unsupervised Learning is a strategy that is required when the correct output is unknown and no teacher is available. Because of this, the NN must organize itself [57]. [55] makes a distinction between 2 different classes of unsupervised learning:

- reinforced learning
- competitive learning

Reinforced learning adjusts the weights in such a way, that desired output is reproduced. An example is a robot in a maze: If the robot can drive straight without any hindrances, it can associate this sensory input with driving straight (desired outcome). As soon as it approaches a turn, the robot will hit a wall (non-desired outcome). To prevent it from hitting the wall it must turn, therefore the weights of turning must be adjusted to the sensory input of being at a turn. Another example is *Hebbian learning* (see [55] for further information).

In competitive learning, the single neurons compete against each other for the right to give a certain output for an associated input. Only one element in the NN is allowed to answer, so that other, competing neurons are inhibited [55].

2.2.2 The Perceptron

The perceptron was invented by Rosenblatt at the Cornell Aeronautical Laboratory in 1957 [56]. It is the computational model of a single neuron and as such, the simplest NN possible [57]. A perceptron consists of one or more inputs, a processor and a single output (see fig. 2.8) [56].

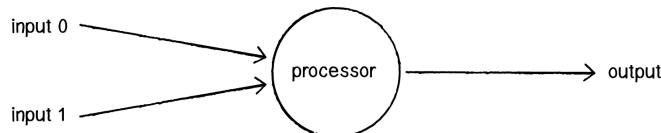

Figure 2.8: Perceptron by Rosenblatt (source: [57])

This can be directly compared to the neuron in fig. 2.6, where:

- input = dendrites
- processor = cell
- output = axon

A perceptron is only capable of solving *linearly separable* problems, such as logical *AND* and *OR* problems. To solve non-linearly separable problems, more than one perceptron is required [56]. Simply put, a problem is linearly separable, if it can be solved with a straight line (see fig. 2.9), otherwise it is considered a non-linearly separable problem (see fig. 2.10).

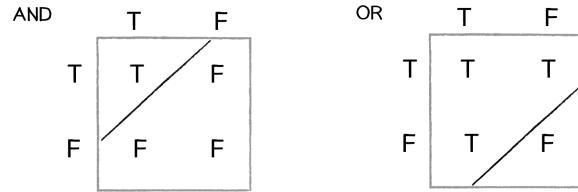

Figure 2.9: Examples for linearly separable problems (source: [57])

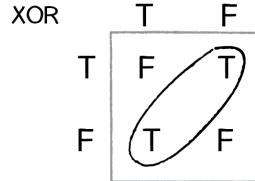

Figure 2.10: Examples for non-linearly separable problems (source: [57])

2.2.3 Multi-layered Neural Networks

To solve more complex problems, multiple perceptrons can be connected to form a more powerful NN. A single perceptron might not be able to solve *XOR*, but one perceptron can solve *OR*, while the other can solve $\neg AND$. Those two perceptrons combined can solve *XOR* [57].

If multiple perceptrons get combined, they create layers. Those layers can be separated into 3 distinct types [8]:

- input layer
- hidden layer
- output layer

A typical NN will have an input layer, which is connected to a number of hidden layers, which either connect to more hidden layers or, eventually, an output layer (see fig. 2.11 for a NN with one hidden layer).

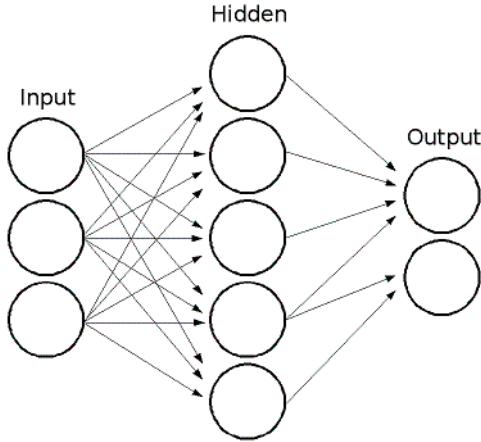

Figure 2.11: NN with multiple layers (source: http://docs.opencv.org/2.4/_images/mlp.png)

As the name suggests, the input layer gets provided with the raw information input. Depending on the internal weights and connections inside the hidden layer, a representation of the input information gets formed. At last, the output layer generates output, again based on the connections and weights between the hidden and output layer [8].

Training this kind of NN is much more complicated than training a simple perceptron, since weights are scattered all over the NN and its layers. A solution to this problem is called *backpropagation* [57].

Backpropagation

Training is an optimization process. To optimize something, a metric to measure has to be established. In the case of backpropagation, this metric is the accumulated output error of the NN to a given input¹¹. There are several ways to calculate this error, with the *mean square error*¹² being the most common one [12].

Finding the optimal weights is an iterative process of the following steps:

1. start with training set of data with known output

¹¹To do so, it is necessary to know the right answer. Therefore, backpropagation is part of the supervised learning process.

¹²Mean square error is the average of the square of the differences of two variables, in this case the expected and the actual output.

2. initialize weights in NN
3. for each set of input, feed the NN and compute the output
4. compare calculated with known output
5. adjust weights to reduce error

There are 2 possibilities in how to proceed. The first one is to compare results and adjust weights after each input/output-cycle. The second one is to calculate the accumulated error over a whole iteration of the input/output-cycle. Each of those iterations is known as an *epoch* [12].

2.3 Microservices

The following section elaborates on the concept of *Microservices* (MS), defining what they are, listing their advantages and disadvantages, as well as explaining why this approach was chosen over a monolithic approach. A monolithic software solution is described by [44] as follows:

”[...] a monolithic application [is] built as a single unit. Enterprise Applications are often built in three main parts: a client-side user interface (consisting of HTML pages and javascript running in a browser on the user’s machine) a database (consisting of many tables inserted into a common, and usually relational, database management system), and a server-side application. The server-side application will handle HTTP requests, execute domain logic, retrieve and update data from the database, and select and populate HTML views to be sent to the browser. This server-side application is a monolith - a single logical executable. Any changes to the system involve building and deploying a new version of the server-side application.”

2.3.1 Definition

MS are an interpretation of the Service Oriented Architecture. The concept is to separate one monolithic software construct into several smaller, modular pieces of software [59]. As such, MS are a modularization concept. However, they differ from other such concepts, since MS are independent from each other. This is a trait, other modularization concepts usually lack [59]. As a result, changes in one MS don’t bring up the necessity of deploying the whole product cycle again, but just the one service. This can be achieved by turning each MS into an independent process with its own runtime [44].

This modularization creates an information barrier between different MS. Therefore, if MS need to share data or communicate with each other, light weight communication mechanisms must be established, such as a RESTful API [54].

Even though MS are more a concept than a specific architectural style, certain traits are usually shared between them [54]. According to [54] and [44], those are:

- (a) **Componentization as a Service:** bringing chosen components (e.g. external libraries) together to make a customized service
- (b) **Organized Around Business Capabilities:** cross-functional teams, including the full range of skills required to achieve the MS goal
- (c) **Products instead of Projects:** teams own a product over its full lifetime, not just for the remainder of a project
- (d) **Smart Endpoints and Dumb Pipes:** each microservice is as decoupled as possible with its own domain logic
- (e) **Decentralized Governance:** enabling developer choice to build on preferred languages for each component.
- (f) **Decentralized Data Management:** having each microservice label and handle data differently
- (g) **Infrastructure Automation:** including automated deployment up the pipeline
- (h) **Design for Failure:** a consequence of using services as components, is that applications need to be designed so that they can tolerate the failure of single or multiple services

Furthermore, [7] defined 5 architectural constraints, which should help to develop a MS:

(1.) **Elastic**

The elasticity constraint describes the ability of a MS to scale up or down, without affecting the rest of the system. This can be realized in different ways. [7] suggests to architect the system in such a fashion, that multiple stateless instances of each microservice can run, together with a mechanism for service naming, registration, and discovery along with routing and load-balancing of requests.

(2.) **Resilient**

This constraint is referring to the before mentioned trait (h) - *Design for Failure*. The failure of or an error in the execution of a MS must not impact other services in the system.

(3.) **Composable**

To avoid confusion, different MS in a system should have the same way of identifying, representing, and manipulating resources, describing the API schema and supported API operations.

(4.) **Minimal**

A MS should only perform one single business function, in which only semantically closely related components are needed.

(5.) **Complete**

A MS must offer a complete functionality, with minimal dependencies to other services. Without this constraint, services would be interconnected again, making it impossible to upgrade or scale individual services.

2.3.2 Advantages and Disadvantages

One big advantage of this modularization is that each service can be written in a different programming language, using different frameworks and tools. Furthermore, each microservice can bring along its own support services and data storages. It is imperative for the concept of modularization, that each microservice has its own storage of which it is in charge of [59].

The small and focused nature of MS makes scaling, updates, general changes and the deployment process easier. Furthermore, smaller teams can work on smaller code bases, making the distribution of know-how easier [54].

Another advantage is how well MS plays into the hands of agile, scrum and continuous software development processes, due to their previously discussed inherent traits.

The modularization of MS doesn't only yield advantages. Since each MS has its own, closed off data management¹³, interprocess communication becomes a necessity. This can lead to communicational overhead which has a negative impact on the overall performance of the system [59].

2.3.1(e) (*Decentralized Governance*) can lead to compatibility issues, if different developer teams chose to use different technologies. Thus, more communication and social compatibility between teams is required. This can lead to an unstable system which makes the deployment of extensive workarounds necessary [54].

It often makes sense to share code inside a system to not replicate functionality which is already there and therefore increase the maintenance burden. The independent nature of MS can make that very difficult, since shared libraries must be build carefully and with the fact in mind, that different MS may use different technologies, possibly creating dependency conflicts.

2.3.3 Conclusion

The tools needed to achieve the research objective stated in subsection 1.2 will be implemented by using the MS modularization patterns. Due to the implementation being done by a single person, some of the inherent disadvantages of MS are negated (making them a favorable modularization concept):

¹³See subsection 2.3.1 - *Decentralized Data Management*

- Interprocess communication doesn't arise between the single stages of the process chain, since they have a set order¹⁴
- Different technologies may be chosen for the single steps of the process chain, however, working alone on the project makes technological incompatibilities instantly visible
- The services shouldn't share functionality, therefore there should be no need for shared libraries

This makes the advantages outweigh the disadvantages clearly:

- different languages and technologies can be used for every single step of the process chain, making the choice of the most fitting tool possible
- WSIs take a heavy toll on memory and disk space due to their size; the use of MS allows each step of the chain to handle those issues in the most suitable way for each given step
- separating the steps of the process chain into multiple MS leads to well separated modules, each having a small and therefore easy to maintain codebase
- other bachelor/master students may continue to use or work on this project in the future, making the benefit of a small, easily maintainable code base twice as important

2.4 Process Chain

This section and its following subsections are dedicated to establish the process chain necessary to accomplish the research objectives stated in 1.2. The usual procedure look as follows:

- (1.) convert chosen WSI img_i^{wsi} to open format img_i^{cvrt}
- (2.) open img_i^{cvrt} in a viewer V
- (3.) annotate img_i^{cvrt} in V
- (4.) persist annotations A_i on img_i^{cvrt} in a file $f_{(A_i)}$
- (5.) create training sample ts_i by extracting the information of A_i in correspondence to img_i^{cvrt}

While it only makes sense to run (1.) once per img_i^{wsi} to create img_i^{cvrt} , steps (2.) - (4.) can be repeated multiple times, so that there is no need to finish the annotation of an image in one session. That makes it necessary to

¹⁴E.g. it wouldn't make sense trying to extract a training sample without converting or annotating a WSI first.

not only save but also load annotations. Therefore, the loading of already made annotations can be added as step (2.5). This also enables the user of editing and deleting already made annotations. Because of this, step (5.) also needs to be repeatable (see fig. 2.12).

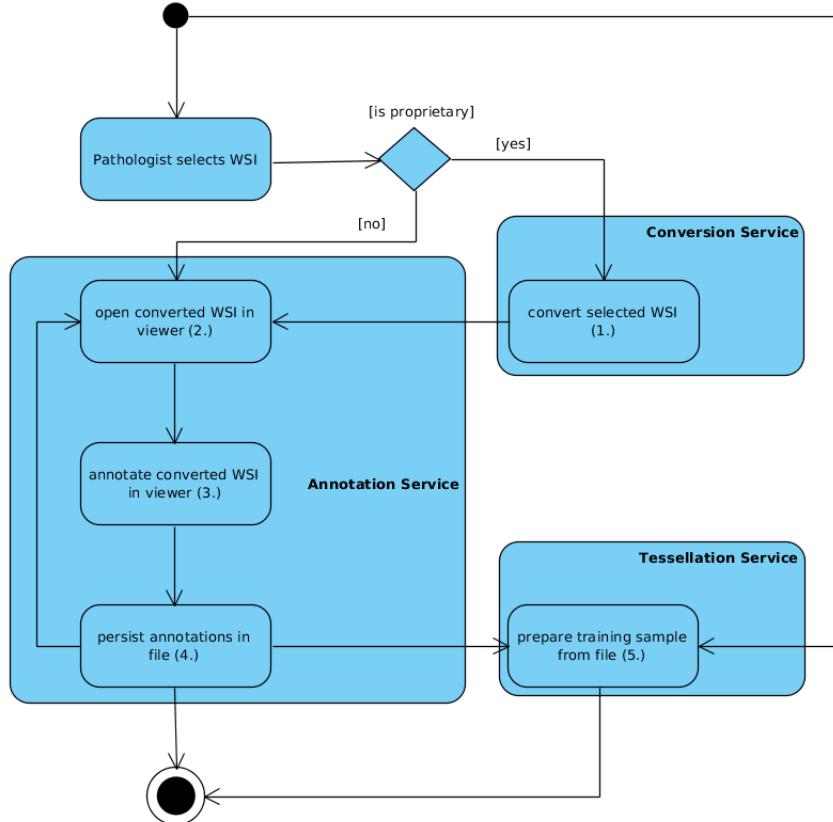

Figure 2.12: Activity diagram of the process chain

The single steps of the process chain will be sorted into semantic groups. Each group will be realized as its own MS. The semantic groups are: conversion (1.), extraction (5.) and viewing and annotation (2. - 4.).

A MS will be introduced for each group in the subsections 2.4.1 - 2.4.3). Those are:

- **Conversion Service**

This service will be responsible of the conversion from img_i^{wsi} to img_i^{cvrt} (1.).

- **Annotation Service**

This service will offer a GUI to view a img_i^{cvrt} , as well as make and manage annotations (2. - 4.)

- **Tessellation Service**

This service will be responsible for extracting a ts_i from a given A_i and img_i^{cvrt} (5.).

2.4.1 Conversion Service

The devices which create WSIs, so called *whole slide scanners*, create images in various formats, depending on the vendor's system (due to the lack of standardization [9]). The Conversion Service (CS) has the goal of converting those formats to an open format¹⁵ (see fig. 2.13).

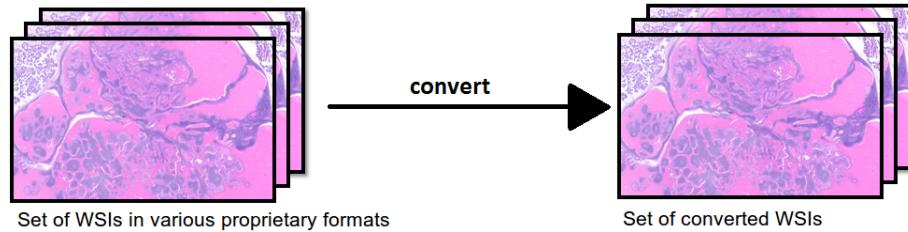

Figure 2.13: Visualization of the Conversion Service

Upon invocation, the CS will take every single WSI inside a given directory and convert it to a chosen open format. The output of each conversion will be saved in another specified folder. Valid image formats for conversion are:

- .bif
- .mrxs
- .ndpi
- .scn
- .svs
- .svslide
- .tif
- .tiff

¹⁵Compare subsections 2.1.2 and 2.1.3

- .vms

- .vmu

2.4.2 Annotation Service

As mentioned in 2.4, the Annotation Service (AS) will provide a graphical user interface (GUI) to view a WSI, create annotations and manage those annotations. This also includes persisting made annotations in a file (see fig. 2.14).

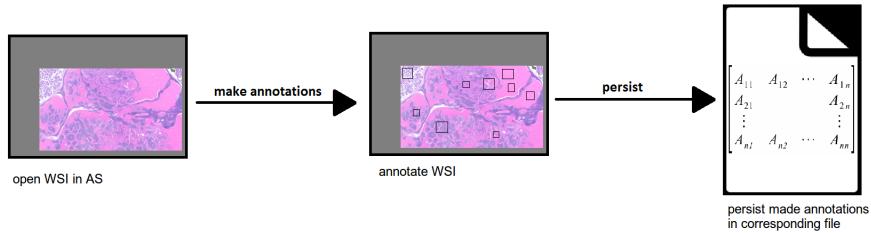

Figure 2.14: Visualization of the Annotation Service

The supplied GUI will offer different tools to help the user annotate the WSI, e.g. a ruler to measure the distance between two points. The annotations themselves will be made via drawing a contour around an object of interest and putting a specified label on that region. To ensure uniformity of annotations, labels will not be added in free text. Instead they will be selected from a predefined dictionary.

2.4.3 Tessellation Service

The task of the Tessellation Service (TS) is to extract annotations and their corresponding image data in such a fashion that they will become usable as training samples for NN.

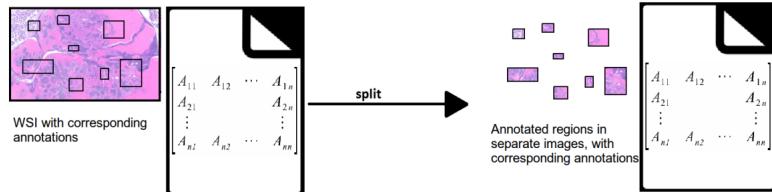

Figure 2.15: Visualization of the Tessellation Service

Let there be a WSI Img and a corresponding set of annotations A . The TS will achieve the extraction by iterating over every $a_i \in A$, creating a sub-image

img_i which is the smallest bounding box around the region described by a_i (see fig. 2.15). To be used as training sample, the TS must keep up the relationship between img_i and a_i .

Chapter 3

Conversion Service

3.1 Methodology

As stated in 2.1, there is no standardized format for WSIs. Supplement 145 of the DICOM standard tries to unify the whole process around WSIs, but vendors still push their proprietary formats. For the reasons mentioned in 2.1.3, it is necessary to establish a common format for all the WSIs which are subject to the process chain established in 2.4. Therefore, the goal of the CS is to convert WSIs of proprietary formats into a common open format.

To make the conversion as convenient and fast as possible, the CS should only have brief user interaction. For this purpose it will not have a GUI. Instead the CS will be implemented as a console script. Furthermore, the CS should be capable of converting multiple WSIs after one another, so that no restart is necessary between conversions. Therefore, the CS will take an input directory as parameter and convert all WSIs of valid format inside that directory. Another parameter will be the output folder, in which the converted DZIs are stored.

vendor	formats
Aperio	SVS, TIF
Hamamatsu	VMS, VMU, NDPI
Leica	SCN
3DHistech/Mirax	MRXS
Philips	TIFF
Sakura	SVSLIDE
Trestle	TIF
Ventana	BIF, TIF

Table 3.1: File formats by vendor

Tab. 3.1 gives an overview of file formats, sorted by vendor, which are viable as input for the conversion.

3.1.1 Selection of Image Format

tool	description	image format
Deep Zoom Composer	dekstop app for Windows	DZI
Image Composite Editor	panoramic image stitcher from Microsoft Research for the Windows desktop	DZI
DeepZoomTools.dll	.NET-library, comes with Deep Zoom Composer	DZI
deepzoom.py	Python	DZI
deepzoom	Perl utility	DZI
PHP Deep Zoom Tools	PHP	DZI
Deepzoom	PHP	DZI
DZT	an image slicing library and tool written in Ruby	DZI
MapTiler	desktop app for Windows, Mac, Linux	TMS
VIPS	command line tool and library for a number of languages	DZI
Sharp	Node.js, uses VIPS	DZI
MagickSlicer	shell script (Linux/Mac)	DZI
Gmap Uploader Tiler	C++	DZI
Node.js Deep Zoom Tools	Node.js, under construction	DZI
OpenSeaDragon DZI Online Composer	Web app (and PERL and PHP scripts)	DZI
Zoomable	service, offers embeds; no explicit API	DZI
ZoomHub	service, under construction	DZI
Kakadu	C++ library to encode or decode JPEG 2000 images	IIIF
PyramidIO	Java (command line and library)	DZI

Table 3.2: Overview of conversion options for zooming image formats (source: [36])

A format or service must be chosen as conversion target for the CS. Choices have been established in 2.1.3. These are:

- (1) BigTIFF
- (2) DZI
- (3) IFFF
- (4) JPEG 2000
- (5) TMS/OMS

To convert a WSI, a conversion tool is needed. Tab. 3.2 shows a listing of possibilities for that purpose. Listed are the name of the tool, the technology used and the output format. The table indicates, that DZI has a great variety of options, while the alternatives have little to none (Map Tiler for TMS, Kakadu for IFFF and none for the others).

Since the CS should only consist of brief user interaction and be as automated as possible, desktop and web applications are not valid as tools for conversion. This excludes *Deep Zoom Composer*, *MapTiler*, *OpenSeaDragon DZI Online Composer* and *Zoomable* as possible choices (therefore also excluding (next to the reasons given in subsection 2.1.3), TMS as possible format).

One of the reasons not to use proprietary formats was the support of only certain operating systems, eliminating Windows-only tools. Those are *Image Composite Editor* and *DeepZoomTools.dll*.

Furthermore, reading the proprietary formats is a highly specialized task, eliminating most of the leftover choices: *deepzoom* [5], *DZT* [17], *sharp* [34], *MagickSlicer*, *Node.js Deep Zoom Tools*¹, *Gmap Uploader Tiler* [51], *Zoomhub* [35] and *PyramidIO* [31].

Kakadu can only encode and decode JPEG 2000 images [36], making it no valid choice either.

This leaves *deepzoom.py* and *VIPS*, both creating DZI as output. Through the use of OpenSlide, they are both capable of reading all proprietary formats stated in tab. 3.1 [53].

3.1.2 Deepzoom.py

*Deepzoom.py*² is a python script and part of Open Zoom³. It can either be called directly over a terminal or imported as a module in another python script. The conversion procedure itself is analogous for both methods.

If run in a terminal the call looks like the following:

```
1 $ python deepzoom.py [options] [input file]
```

¹MagickSlicer and Node.js Deep Zoom Tools use ImageMagick to read images, which doesn't support any of the proprietary WSI formats [38].

²See <https://github.com/openzoom/deepzoom.py> for further details

³See <https://github.com/openzoom> for further details

The various options and their default values can be seen in tab. 3.3. If called without a designated output destination, deepzoom.py will save the converted DZI in the same directory as the input file.

option	description	default
-h	show help dialog	-
-d	output destination	-
-s	size of the tiles in pixels	254
-f	image format of the tiles	jpg
-o	overlap of the tiles in pixels (0 - 10)	1
-q	quality of the output image (0.0 - 1.0)	0.8
-r	type of resize filter	antialias

Table 3.3: Options for deepzoom.py

The resize filter is applied to interpolate the pixels of the image when changing its size for the different levels. Supported filters are:

- cubic
- bilinear
- bicubic
- nearest
- antialias

When used as module in another python script, deepzoom.py can simply be imported via the usual *import* command. To actually use deepzoom.py, a Deep Zoom Image Creator needs to be created. This class will manage the conversion process:

```

1 # Create Deep Zoom Image Creator
2 creator = deepzoom.ImageCreator(tile_size=[size],
3     tile_overlap=[overlap], tile_format=[format],
4     image_quality=[quality], resize_filter=[filter])

```

The options are analogous with the terminal version (compare tab. 3.3). To start the conversion process, the following call must be made within the python script:

```

1 # Create Deep Zoom image pyramid from source
2 creator.create([source], [destination])

```

In the proposed workflow, the ImageCreator opens the input image img^{wsi} and accesses the information necessary to create the describing XML file for the DZI⁴. The needed number of levels is calculated next. For this, the bigger value

⁴Compare chap. 2.1.3

of height or width of img^{wsi} is chosen (see eq. 3.1) and then used to determine the number of levels lvl^{max} (see eq. 3.2) necessary.

$$max_dim = max(height, width) \quad (3.1)$$

$$lvl^{max} = \lceil \log_2(max_dim) + 1 \rceil \quad (3.2)$$

Once lvl^{max} has been determined, a resized version img_i^{dzi} of img^{wsi} will be created for every level $i \in [0, lvl - 1]$. The quality of img_i^{dzi} will be reduced according to the value specified for -q/image_quality (see tab. 3.3). The resolution of img_i^{dzi} will be calculated with the *scale* function (see eq. 3.3) for both, height and width. Furthermore, the image will be interpolated with the specified filter (-r/resize_filter parameter, see tab. 3.3).

$$scale = \lceil dim * 0.5^{lvl^{max}-i} \rceil \quad (3.3)$$

Once img_i^{dzi} has been created, it will be tessellated into as many tiles of the specified size (-s/tile_size parameter, see tab. 3.3) and overlap (-o/tile_overlap parameter, see tab. 3.3) as possible. If the size of img^{wsi} in either dimension isn't a multiple of the tile size, the last row/column of tiles will be smaller by the amount of (*tile size* - ([height or width] mod *tile size*)) pixels.

Every tile will be saved as [column]_[row].[format] (depending on the -f/file_format parameter, see tab. 3.3) in a directory named according to the corresponding level i . Each one of those level directories will be contained within a directory called [filename]_files. The describing XML file will be persisted as [filename].dzi in the same directory as [filename]_files.

3.1.3 VIPS

VIPS (VASARI Image Processing System) is described as "[...] a free image processing system [...]" [11]. It includes a wide range of different image processing tools, such as various filters, histograms, geometric transformations and color processing algorithms. It also supports various scientific image formats, especially those needed by the CS⁵ [11]. One of the strongest traits of VIPS is its speed and little data usage compared to other imaging libraries [42].

VIPS consists of two parts: the actual library (called libvips) and a GUI (called nip2). libvips offers interfaces for C, C++, python and the command line. The GUI will not be further discussed, since it is of no interest for the implementation of the CS.

VIPS speed and little data usage is achieved by the usage of a fully demand-driven image input/output system. While conventional imaging libraries queue their operations and go through them sequentially, VIPS awaits a final write command, before actually manipulating the image. All the queued operations will then be evaluated and merged into a few single operations, requiring no

⁵See chap. 2.2.1

additional disc space for intermediates and no unnecessary disc in- and output. Furthermore, if more than one CPU is available, VIPS will automatically evaluate the operations in parallel [41].

As mentioned before, VIPS has a command line and python interface. In either case, a function called *dzsave* will manage the conversion from a WSI to a DZI. A call in the terminal looks as follows:

```
1 $ vips dzsave [input] [output] [options]
```

When called, VIPS will take the image [input], convert it into a DZI and then save it to [output]. The various options and their default values can be seen in tab. 3.4.

option	description	default
layout	directory layout (allowed: dz, google, zoomify)	dz
overlap	tile overlap in pixels	1
centre	center image in tile	false
depth	pyramid depth	onepixel
angle	rotate image during save	d0
container	pyramid container type	fs
properties	write a properties file to the output directory	false
strip	strip all metadata from image	false

Table 3.4: Options for VIPS

A call in python has the same parameters and default values. It looks like this:

```
1 image = Vips.Image.new_from_file(input)
2 image.dzsave(output[, options])
```

In line 1 the image gets opened and saved into a local variable called *image*. While being opened, further operations could be done. The command in line 2 writes the processed image as DZI into the specified output location.

3.2 Implementation

As stated before, the CS should be implemented as a script.

The first iteration was a python script using deepzoom.py for the conversion. This caused severe performance issues. Out of all the image files in the test set⁶, only one could be converted⁷. Other files were either too big, so the process would eventually be killed by the operating system, or exited with an IOError concerning the input file from the PIL imaging library.

⁶See chap. 3.3

⁷CMU-3.svs from Aperio, see Appendix A

The second iteration uses VIPS python implementation, which is not only faster than deepzoom.py (**citation or data needed**), but also capable of converting all the given test images.

The script has to be called inside a terminal in the following fashion:

```
1 $ python ConversionService.py [input dir] [output dir]
```

Both the input and the output directory parameter are mandatory, in order for the script to know where to look for images to convert and where to save the resulting DZIs.

Upon calling, the *main()* routine will be started, which orchestrates the whole conversion process. The source code is as follows:

```
1 def main():
2     path = checkParams()
3     files = os.listdir(path)
4     for file in files:
5         print("-----")
6         extLen = getFileExt(file)
7         if(extLen != 0):
8             print("converting " + file + "...")
9             convert(path, file, extLen)
10            print("done!")
```

checkParams() checks if the input parameters are valid and, if so, returns the path to the specified folder or aborts the execution otherwise. Furthermore, it will create the specified output folder, if it doesn't exist already. In the next step, the specified input folder will be checked for its content. *getFileExt(file)* looks up the extension of each contained file and will either return the length of the files extension or 0 otherwise. Each valid file will then be converted with the *convert(...)* function:

```
1 # convert image source into .dzi format and copies all header
2 # information into [img]-files dir as metadata.txt
3 # param path: directory of param file
4 # param file: file to be converted
5 # param extLen: length of file extension
6 def convert(path, file, extLen):
7     dizi = OUTPUT + file[:extLen] + ".dzi"
8     im = Vips.Image.new_from_file(path + file)
9     # get image header and save to metadata file
10    im.dzsave(dizi, overlap=OVERLAP, tile_size=TILESIZE)
11    # create file for header
12    headerOutput = OUTPUT + file[:extLen-1] + "-files/metadata.txt"
13    bashCommand = "touch " + headerOutput
14    call(bashCommand.split())
15    # get header information
16    bashCommand = "vipsheader -a " + path + file
17    p = subprocess.Popen(bashCommand.split(), stdout=subprocess.PIPE,
18                         stderr=subprocess.PIPE)
19    out, err = p.communicate()
20    # write header information to file
21    text_file = open(headerOutput, "w")
22    text_file.write(out)
23    text_file.close()
```

The name for the new DZI file will be created from the original file name, however, the former extension will be replaced by "dzi" (see line 7). *OUTPUT* specifies the output directory which the file will be saved to. Next, the image file will be opened with Vips' Image class. Afterwards, *dzsave(...)* will be called, which handles the actual conversion into the dzi file format. *OVERLAP* and *TILESIZE* are global variables which describe the overlap of the tiles and their respective size. Their values are 0 (*OVERLAP*) and 256 (*TILESIZE*). The output will be saved to the current working directory of *ConversionService.py*, appending "/dzi/[*OUTPUT*]".

When a WSI gets converted into DZI by the CS, most of the image header information is lost. To counteract this, a file *metadata.txt* is created in the [name].files directory, which serves as container for the header information of the original WSI (see line 12 and 13).

The console command *vipsheader -a* is responsible for extracting the header information (see line 17 - 18). The read information (*out* in line 18) is then written into the *metadata.txt* file (Line 20 - 22).

3.3 Test

To test the correct functionality of the CS a test data set was needed. OpenSlide offers a selection of freely distributable WSIs⁸, which can be used for that purpose.

Since the size of the WSIs is big, they are not delivered via the CS repository⁹. Instead they need to be downloaded separately from the OpenSlide homepage. For a complete listing of the used test data see Appendix A.

3.3.1 Setup

To create a controlled environment for the test, a new directory will be created, called *CS_test*. A copy of *ConversionService.py* as well as a directory containing all the test WSIs (called *input*) will be placed in that directory.

Input contains the following slides:

- (1) CMU-2 (Aperio, .svs)
- (2) CMU-1 (Generic Tiled tiff, .tiff)
- (3) OS-3 (Hamamatsu, .ndpi)
- (4) CMU-2 (Hamamatsu, .vms)
- (5) Leica-2 (Leica, .scn)
- (6) Mirax2.2-3 (Mirax, .mrxs)

⁸See OpenSlides Homepage: <http://openslide.cs.cmu.edu>, or directly for the test data: <http://openslide.cs.cmu.edu/download/openslide-testdata/>

⁹see <https://github.com/SasNaw/ConversionService>

(7) CMU-2 (Trestle, .tif)

(8) OS-2 (Ventana, .bif)

Because of their structure, (4), (6) and (7) will be placed in directories titled with their file extension. Fig. 3.1 shows the content of the input folder.

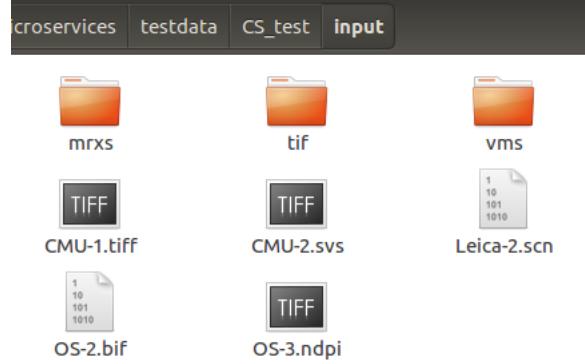

Figure 3.1: Content of input directory

This makes multiple calls of the CS necessary. The calls, in that order, are:

```
1 $ python ConversionService.py input/ out_1/
2 $ python ConversionService.py input/mrxs out_2/
3 $ python ConversionService.py input/tif out_3/
4 $ python ConversionService.py input/vms out_4/
```

3.3.2 Result

All runs of `ConversionService.py` were successful. Tab. 3.5 shows an overview of the results:

input	output	time (sec)
input/	CMU-1.dzi, CMU-2.dzi, Leica-2.dzi, OS-2.dzi, OS-3.dzi	1992
input/mrxs/	Mirax2.2-3.dzi	500
input/tif/	CMU-2.dzi	56
input/vms/	CMU-2-40x - 2010-01-12 13.38.58.dzi	305

Table 3.5: Results of Conversion Service Test

The vast difference in file size of the test data accounts for the different run times of the tests. While the first test converted 5 WSIs (399 sec/WSI), every other test converted a single one. The conversion of (6) was much faster, since

the file was smaller in size (304.22 MB) compared to the others (1495.24 MB on average).

Chapter 4

Annotation Service

4.1 Objective of the Annotation Service

As described in 2.4.2, the goal of the AS is to provide a user with the possibility to:

- (1) view A WSI
- (2) annotate a WSI
- (3) manage made annotations

In order to achieve objective (1) - (3), a GUI needs to be deployed which supports the user in working on those tasks. (3) also adds the need for file persistence management.

During the development process it became clear that supporting only DZI as input format was impractical for the real life environment of the AS. Therefore, the need to support proprietary formats as well arose. The proprietary formats should be supported without implementing separate handling for each one and without creating a vendor lock-in or platform restriction¹.

4.2 Methodology

As stated in 2.1, most vendors have proprietary image formats and their own implementation of a viewer for those, thus creating a vendor lock-in. Further do vendors often support only Windows platforms, ignoring other operating systems [9] [14] [26]. To avoid this, a solution must be found that is independent of operating system and vendor.

Independence from an operating system can be achieved by using web technologies, especially when running an application in a web browser [21], since those are supported by all modern operating systems.

¹see chap. 1.2(i), 1.2(ii) and 2.1.3

Chap. 3 already established a service to convert WSIs of various formats into the DZI format, solving the problem of multiple proprietary formats. But, as the development process has shown, this is not enough. Therefore, a solution must be established, with which proprietary formats can be handled as well. The use of OpenSlides python interface provides the functionality of generating individual Deep Zoom tiles from slide objects without a complete conversion via a DZI wrapper, which can be used to wrap proprietary image formats and serve them to a web browser as if they would be DZI [53].

Because of those reasons, the AS will be implemented as a web browser application.

4.2.1 Functionality of the Annotation Service

The goal of viewing a WSI (1) is a straight forward task. (2) and (3) are more elusive. For that reason, this subsection elaborates on the functionality needed to help achieve those objectives.

Annotations will be created by drawing directly onto the viewed WSI. If the user spots a region of interest, a contour can be drawn around it. This can either be done in *free hand* or *polygon mode*. In free hand mode, the contour will be drawn along the path of the mouse pointer, until the mode is disabled again. Upon deactivation, the contour will be closed. In polygon mode, the user can place coordinates which will be connected from one to another in the order they're placed in. A contour in this mode considers to be closed, once a point on the contour is clicked a second time. A marked region of interest is simply called *region* from this point on.

The information what a region is surrounded by can be as valuable as the information about the region itself [4]. Therefore, every region will have a *context* trait, which lists every label of regions it touches, crosses, surrounds or is surrounded by (see fig. 4.1).

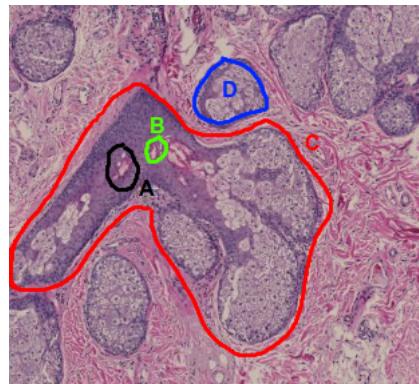

Figure 4.1: Example of context regions (B, C are context of A; A, C are context of B; A, B are context of C; D has no context region)

Another way of creating regions will be so called *points of interest* (POI). A POI will be placed with a mouse click. After that, an external script will be invoked to run an automated segmentation in the proximity of the POI and return with a contour which will be marked as region. The segmentation approaches may differ drastically in different scenarios [47], therefore the script will be interchangeable².

Each region has a *label* associated to it. A label is a predefined string, which describes what the region just created shows. The labels available will be determined through a *label dictionary*, which is a container that offers a list of strings to select from. This approach guarantees a unified labeling, independent of a specific WSI or pathologist. The option to choose between multiple available label dictionaries opens up the possibility of creating dictionaries which are specialized on certain cases or studies. Again, to keep up labeling integrity, labels can only be selected from one dictionary per WSI.

Users will be able to create new, empty dictionaries, if the need arises. Furthermore, they will be able to add entries to existing and new dictionaries alike, to further advance or specialize them. To delete single entries or whole dictionaries, file access to the server is necessary. This is due to the fact, that knowledge can be added without direct negative consequences. Deleting existing knowledge influences all WSIs on which this knowledge was used, may it be as a label or a whole dictionary.

To support the user in annotating a WSI, a distance measurement tool will be usable as well. This tool can measure the distance between 2 pixels in μm .

4.2.2 Parts of the Annotation Service

The AS is implemented in 2 parts. Those are the Annotation Service Server (ASS) and the Annotation Service Viewer (ASV).

This is because of the *same-origin policy* (SOP). SOP is a security concept of the web application security model. It prevents a direct access to files, if the parent directory of the originating file is not an ancestor directory of the target file [49]. Because of the SOP, WSIs would have to be located in the directory structure of the AS, which by itself doesn't create a problem. To get a new WSI there, however, the user would be forced to navigate through the structure of the AS, find the correct directory and then place it there manually. This makes knowledge of the service structure necessary and creates a horrible UX. Furthermore, tinkering with the file structure of the AS creates a possible source for errors.

A workaround of this problem is to deploy a web server, which can redirect the image request, access the WSI and return it in response [21]. The use of DZI creates another advantage: the used image pyramid model reduces the network traffic necessary to load and show a WSI in a viewer [9] [14].

²There are many different ways of how to approach the topic of segmentation (e.g. [22], [23], [29], [43] for cell segmentation alone). Writing a fully working segmentation script is worth another thesis by itself, therefore only a dummy implementation will be delivered with this work.

Furthermore, even a single WSI takes up a lot of storage capacity [27]. Having multiple WSIs on a local hard drive would either create the need for huge amounts of available storage space or restrict the amount of accessible WSIs to a few at any given time. The latter solution would create two follow-up problems:

- WSIs are medical images and as such confidential information. Therefore, not everyone is allowed to just have access to or copies of them [52] [58]. Once a copy of a WSI changes hands, it is virtually impossible to make sure that privacy regulations will be upheld.
- With only a small amount out of all WSIs accessible at all times, the need for copying files back and forth arises as soon as the user wants to compare, update or correct a WSI, which is not on his local file system at the given moment. Not only is this a great source for possible errors, but also very time consuming and inefficient.

With the use of a web server as a central image repository, WSIs and the access to them can be managed in a centralized spot, while upholding confidentiality regulations. Furthermore, a user has access to all of her/his WSIs at any given time, without the need for creating subsets and copying files back and forth. Depending on the setup of the network, other factors can come into play as well. Access to and sharing of rare cases, educational material and training samples can be granted without a complicated distribution chain and a smaller risk for confidentiality issues. It also enables the consultation of case experts independent of their physical position on the planet [20].

Annotation Service Server

The ASS has 2 main purposes.

First, it serves as a so called *Digital Slide Repository* (DSR). A DSR manages storage of WSIs and their metadata. Additionally, it serves requested image data to a viewer client [9], such as the ASV.

Second, it is responsible for file management. In detail, this means:

- persist made annotations in a file
- deliver annotation data together with image data
- serve list of all available label dictionaries
- serve label dictionary entries
- save added entries to existing label dictionary
- create new, empty label dictionaries

The development of a fully functional web server isn't in the scope of this thesis. Therefore, the ASS will run as a local web server. This works around many of the common issues when hosting a web server [2], such as:

- inefficient data or page caching
- firewall throughput
- internet access throughput
- load balance issues
- gateway issues
- poor security design
- connectivity issues

Annotation Service Viewer

The ASV is developed to deploy a GUI through which the pathologist is enabled to view a WSI and annotate it. The ASV is developed in an iterative approach with the help of selected pathologists. After each iteration, the GUI and user experience (UX) will be evaluated. This way, the ASV can be adapted to the needs of a real life environment based on the pathologists feedback.

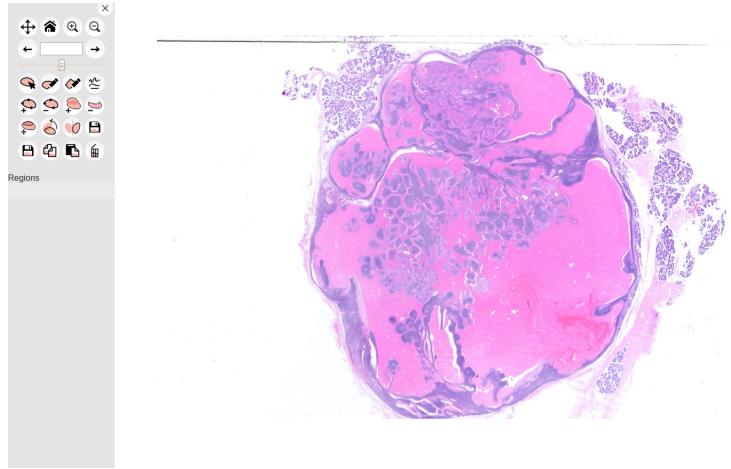

Figure 4.2: Microdraw GUI with opened WSI

The first iteration of the ASV will be based on an open source project called *MicroDraw*³ (see fig. 4.2 for MicroDraws GUI). MicroDraw is a web application to view and annotate "*high resolution histology data*" [3]. The visualization is based on another open source project, called *OpenSeadragon* [36]. Annotations are made possible by the use of *Paper.js*⁴. This delivers a baseline for the

³See <https://github.com/r03ert0/microdraw> for more information on the MicroDraw project

⁴see <http://paperjs.org/> for more information on Paper.js

functionality specified in 4.2.1 and can be further adjusted to the needs of the ASV.

Apart from the frameworks used, MicroDraw is written in JavaScript using HTML5, CSS3 and jQuery⁵.

4.3 Annotation Service Server Implementation

The ASS is a local RESTful server written in python (*as_server.py*). Additional frameworks have been used to improve functionality. Those are:

- Flask [30] (see chap. 4.3.1)
- OpenSlide Python [53] (see chap. 4.3.2)

The use of the Flask framework makes a certain folder structure necessary [30]. To serve static files, a *"static/"* directory must be present in the base directory of the ASS. The static/ directory contains the CSS, JavaScript, dictionaries and WSIs. To read a WSI with the ASS, it must be placed in static/wsi/[file path/]. The dictionaries can be found in static/dictionaries/, if a manual manipulation of a dictionary (deleting one or deleting/updating an entry in one) becomes necessary.

The ASS can be started from a terminal through the use of a python interpreter:

```
1 $ python as_server.py
```

Alternatively, python's -m switch can be used:

```
1 $ export FLASK_APP=as_server.py
2 $ python -m flask run
```

When started without further parameters, the server will listen to the IP 127.0.0.1, port 5000 by default. Another IP address or port can be specified via the -l and -p parameter (see tab. 4.1 for a complete list of available parameters):

```
1 $ python as_server.py -l 192.27.119.89 -p 4711
```

parameter	description	default
-B, --ignore-bounds	render only the non-empty slide region	false
-e, --overlap	set overlap between adjacent tiles in pixels	0
-f, --format	set tile format (PNG or JPEG)	JPEG
-l, --listen	set IP address to listen to	127.0.0.1
-p, --port	set port to listen to	5000
-Q, --quality	set JPEG compression quality in %	100
-s, --size	set tile size	256

Table 4.1: Parameters for as_server.py

⁵see <https://jquery.com/> for more information on jQuery

To access a WSI, the URL must be pointed to it, e.g. `http://127.0.0.1:5000/wsi/openslide/CMU-1.svs` to access the WSI CMU-1.svs in the directory static/wsi/openslide/.

4.3.1 Flask

To give the ASS its server capabilities, Flask was used. Flask considers itself as “*microframework*”, meaning that the development team tries to keep its core “*simple, but extensible*” [30]. It contains a built-in development server, integrated unit testing, RESTful request dispatching and is fairly easy to set up and use. A minimal Flask application can look like this⁶:

```

1 from flask import Flask
2 app = Flask(__name__)
3
4 @app.route('/')
5 def hello_world():
6     return 'Hello, World!'
7
8 app.run(host='127.0.0.1', port='5000')

```

After the import of the Flask class (line 1), a Web Server Gateway Interface (WSGI) object is created⁷ (line 2). The defined `hello_world` function (line 5 and 6) is annotated with a `route()` *decorator* to bind a specific URL to it (line 4). Once the specified URL is requested, Flask knows which function to invoke. Line 8 starts a local server listening on 127.0.0.1:5000.

As mentioned above, a `route()` *decorator* (see fig. 4.3) binds a URL to a function. When bound, the function will be called, once the specified URL is requested by the client [30].

```

@app.route('/')
def index():
    return 'Index Page'

@app.route('/hello')
def hello():
    return 'Hello, World'

```

Figure 4.3: Hello, World! example on how to use Flasks route() decorator (source: [30])

A bound URL can also contain variable sections, which are marked as `/<variable name>`. Optionally, a converter can be used to only accept variables of a certain type. This becomes possible by specifying the converter in

⁶The example application code snippet is taken from [30]

⁷The WSGI is a standard interface for the communication between web servers and web applications or frameworks in python. The interface has a server and application side. Basically, the server side invokes a callable object that is provided by the application side. The specifics of providing this object are up to the individual server [6].

front of the variable: `/<converter:variable name>` [30]. See tab. 4.2 for the list of available converters in Flask.

name	accepted input
string	any text without a slash (default)
int	integer values
float	floating point values
path	like string, but also accepts slashes
any	matches one of the items provided
uuid	UUID strings

Table 4.2: Available converters in Flask (source: [30])

To bind a URL with one or more variable sections to a function, the corresponding function must have the variable sections as parameters:

```

1 @app.route('/<slug>-files/<int:level>/<int:col>-
2 <int:row>.<format>')
3 def tile(slug, level, col, row, format): ...

```

HTTP knows different methods for accessing URLs. By default, a route only answers to GET requests and refuses every other kind with a 405 HTTP status code. This can be changed by adding the *methods* argument to the `route()` decorator (see fig. 4.4) [30].

```

from flask import request

@app.route('/login', methods=['GET', 'POST'])
def login():
    if request.method == 'POST':
        do_the_login()
    else:
        show_the_login_form()

```

Figure 4.4: Example use of the method argument (source: [30])

Through the use of decorators a RESTful API was deployed for the ASS (compare chap. 4.3.3).

4.3.2 OpenSlide Python

To read WSIs, the ASS uses OpenSlide Python, a python interface to the OpenSlide C library. It provides a simple interface for reading WSI. Additionally, it offers a DZI wrapper [53], called *DeepZoomGenerator* (DZG), which can be used to create Deep Zoom tiles on demand. WSIs of the following formats are supported:

- BIF
- NDPI
- MRXS
- SCN
- SVS
- SVSLIDE
- TIF
- TIFF
- VMS
- VMU

Through OpenSlide, the ASS can read a proprietary WSI as a so called *OpenSlide* object (see line 4). As such it has methods to access available metadata, image tiles, the thumbnail and associated images. This OpenSlide object can be wrapped with a DZG to enable DZI support [53]. To do so, the OpenSlide object needs to be passed into the constructor of the DZG (see line 5), together with a number of optional parameters (see tab 4.3 for parameters and their default values):

```

1 from openslide import open_slide
2 from openslide.deepzoom import DeepZoomGenerator
3
4 slide = open_slide(slide_path)
5 dzg = DeepZoomGenerator(slide[, tile_size, overlap, limit_bounds])

```

parameter	type	description
osr	OpenSlide, ImageSlide	the slide object
tile_size	integer	the width and height of a single tile (254)
overlap	integer	the number of extra pixels to add to each interior edge of a tile (1)
limit_bounds	boolean	true to render only the non-empty slide region (false)

Table 4.3: DeepZoomGenerator parameters (with default values, source: [53])

Once created, the DZG can give numerous informations about the tiles and levels of the wrapped WSI⁸. Of special importance are the *get_dzi* and *get_tile*

⁸see [53] for an in-depth list of functions

functions. The `get_file(format)` function creates a string, containing the metadata of the .dzi-file⁹. The `format` parameter specifies the format of the individual tiles (PNG or JPEG). The `get_tile(level, address)` function returns an image of the tile corresponding to the supplied parameter values (see tab. 4.4). The returned tile is either PNG or JPEG, depending on the value on the value passed to the `format` parameter of the `get_file` function.

name	type	description
level	integer	the DZI level to get the tile from
address	tuple	the address of the tile within the level as a (column, row) tuple

Table 4.4: DeepZoomGenerators `get_tile` parameters (source: [53])

Through the use of those 2 functions, the ASS can create the metadata of a DZI on the fly and pass it to the ASV. The ASV then requests the individual tiles needed for the current view in return, which are generated by the DZG from the original WSI on demand.

4.3.3 Annotation Service Server RESTful API

To communicate with the ASS a RESTful API was deployed. This is realized with Flasks `route()` decorators¹⁰. The listing below gives an overview over the URLs that the ASS RESTful API offers (in the style of **URL** (method): *function(parameters)*), followed by a brief description of the functionality¹¹:

(1) - **/wsi/<path:file_path>.dzi** (GET): *index_dzi(file_path)*

This URL is used to request a viewer with a specified DZI from the ASS. The ASS then renders an ASV and passes the DZIs file path, its microns per pixel (MPP) and its name to it. The ASV feeds the path to OpenSeadragon, which then views the DZI. The MPP are used to calculate the actual image size in μm for the scale. Lastly, the file name is used to change the name of the browser tab accordingly.

(2) - **/wsi/<path:file_path>** (GET): *index_wsi(file_path)*

Works similar to (1), except that the requested image is not of the DZI format. To view it in OpenSeadragon anyway, an instance of the DZG is created which wraps the proprietary WSI. Then, a specific path ("/*slide.dzi*") is handed to the ASV.

(3) - **/<slug>.dzi** (GET): *dzi(slug)*

Once the ASV requests *slide.dzi*, the DZG builds a response with the descriptive DZI file, created from the proprietary WSI format (via its

⁹see chap. 2.1.3 - Deep Zoom Images

¹⁰see chap. 4.3.1

¹¹see Appendix B.1 for a detailed documentation of the ASS functions

`.get_dzi(format)` function, with `format` being the file format of the tiles) and serves it to the ASV.

- (4) - `/<slug>.files/<int:level>_<int:col>_<int:row>.<format>`
(GET): `tile(slug, level, col, row, format)`

If an original DZI is requested, there is a `/wsi/` in front of the URL. Therefore, this URL only triggers if (3) was called before. This way OpenSeadragon requests the separate tiles needed to fill the current view of the user. This is done via the DZG `.get_tile(level, address)` function. `Level` describes the requested level, while `address` is a tuple with the x (col) and y (row) position of the requested tile.

- (5) - `/saveJson` (POST): `saveJson()`

This URL is used when the user wants to save made annotations. The name of the JSON file and the content to write into it will be send via the POST request. The content of the POST request can be accessed via Flasks `Request` object [30] in the following fashion:

```
1 post_data = request.form  
2 source = post_data.get('file', default='')  
3 content = post_data.get('content', default='{}').  
4 encode('utf-8')  
5
```

- (6) - `/loadJson` (GET): `loadJson()`

(6) is used to load a JSON file, may that be the `configuration.json`, a dictionary or saved annotations. The name of the source is passed as parameter (`?src=[file]`) to the ASS. Similar to (5), it can be accessed with the Request object [30]: `request.args.get(parameter, default value)`.

- (7) - `/createDictionary` (GET): `createDictionary()`

If the user sends the command to create a new dictionary, this URL is called. The ASS then creates a new, empty dictionary file. The name of the dictionary is passed as a URL parameter (`?name=[name]`) and then acquired in the same fashion as in (5). The ASS also opens the configuration file and changes the currently selected dictionary to the newly created one.

- (8) - `/getDictionaries` (GET): `getDictionaries()`

When called, the ASS looks up the content of its `dictionaries` folder and returns a list with the found file names or -1 in the case of an error.

Appendix A

Listing of Conversion Service Test Data

The test data for the Conversion Service can be found at OpenSlides homepage, at the freely distributable test data section¹. Various slides can be found there. The following subsections (A.1 - A.8) give listings of all used WSIs, sorted by vendor and file format.

A.1 Aperio (.svs)

name	size (MB)	description
CMU-1-JP2K-33005.svs	126.42	Export of CMU-1.svs, brightfield, JPEG 2000, RGB
CMU-1-Small-Region.svs	1.85	Exported region from CMU-1.svs, brightfield, JPEG, small enough to have a single pyramid level
CMU-1.svs	169.33	Brightfield, JPEG
CMU-2.svs	372.65	Brightfield, JPEG
CMU-3.svs	242.06	Brightfield, JPEG
JP2K-33003-1.svs	60.89	Aorta tissue, brightfield, JPEG 2000, YCbCr
JP2K-33003-2.svs	275.85	Heart tissue, brightfield, JPEG 2000, YCbCr

Table A.1: Aperio data set (source: <http://openslide.cs.cmu.edu/download/openslide-testdata/Aperio/>)

¹<http://openslide.cs.cmu.edu/download/openslide-testdata/>

A.2 Generic Tiled tiff (.tiff)

name	size (MB)	description
CMU-1.tiff	194.66	Conversion of CMU-1.svs to pyramidal tiled TIFF, brightfield

Table A.2: Generic Tiled tiff data set (source: <http://openslide.cs.cmu.edu/download/openslide-testdata/Generic-TIFF/>)

A.3 Hamamatsu (.ndpi)

name	size (MB)	description
CMU-1.ndpi	188.86	Small scan with valid JPEG headers, brightfield, circa 2009
CMU-2.ndpi	382.14	Brightfield, circa 2009
CMU-3.ndpi	270.1	Brightfield, circa 2009
OS-1.ndpi	1,860	H&E stain, brightfield, circa 2012
OS-2.ndpi	931.42	Ki-67 stain, brightfield, circa 2012
OS-3.ndpi	1,370	PTEN stain, brightfield, circa 2012

Table A.3: Hamamatsu data set (.ndpi, source: <http://openslide.cs.cmu.edu/download/openslide-testdata/Hamamatsu/>)

A.4 Hamamatsu (.vms)

name	size (GB)	description
CMU-1.zip	0.62	Brightfield
CMU-2.zip	1.13	Brightfield
CMU-3.zip	0.91	Brightfield

Table A.4: Hamamatsu data set (.vms, source: <http://openslide.cs.cmu.edu/download/openslide-testdata/Hamamatsu-vms/>)

A.5 Leica (.scn)

name	size (GB)	description

Mirax2.2-2.zip	2.38	HPS stain, brightfield, JPEG, CURRENT_SLIDE_VERSION 2.2
Mirax2.2-3.zip	2.77	HPS stain, brightfield, JPEG, CURRENT_SLIDE_VERSION 2.2
Mirax2.2-4-BMP.zip	0.95	Brightfield, BMP, CURRENT_SLIDE_VERSION 2.2
Mirax2.2-4-PNG.zip	1.01	Brightfield, PNG, CURRENT_SLIDE_VERSION 2.2

Table A.6: Mirax data set (source: <http://openslide.cs.cmu.edu/download/openslide-testdata/Mirax/>)

A.7 Trestle (.tiff)

name	size (MB)	description
CMU-1.zip	158.87	Brightfield
CMU-2.zip	304.22	Brightfield
CMU-3.zip	223.11	Brightfield

Table A.7: Trestle data set (source: <http://openslide.cs.cmu.edu/download/openslide-testdata/Trestle/>)

A.8 Ventana (.bif)

name	size (GB)	description
OS-1.bif	3.61	H&E stain, brightfield
OS-2.bif	2.53	Ki-67 stain, brightfield

Table A.8: Trestle data set (source: <http://openslide.cs.cmu.edu/download/openslide-testdata/Trestle/>)

Appendix B

Annotation Service Documentation

The following two sections explain the most important functions of the ASS and ASV in detail.

B.1 Annotation Service Server

B.2 Annotation Service Viewer

List of Figures

1.1	Example results of the in [1] introduced model (source: http://cs.stanford.edu/people/karpathy/deepimagesent/)	4
2.1	DICOMs image pyramid (source: [27])	8
2.2	DZI pyramid model example (source: [50])	12
2.3	Example of iiif request (source: http://www.slideshare.net/Tom-Cramer/iiif-international-image-interoperability-framework-dlf2012?ref=https://www.diglib.org/forums/2012forum/transcending-silos-leveraging-linked-data-and-open-image-apis-for-collaborative-access-to-digital-facsimiles/)	13
2.4	Results of IIIF request with different values for region parameter (source: [24])	15
2.5	Results of IIIF request with different values for size parameter (source: [24])	15
2.6	Neuron in a BNN (source: [57])	18
2.7	Exemplary NN (source: [57])	19
2.8	Perceptron by Rosenblatt (source: [57])	20
2.9	Examples for linearly separable problems (source: [57])	21
2.10	Examples for non-linearly separable problems (source: [57])	21
2.11	NN with multiple layers (source: http://docs.opencv.org/2.4/_images/mlp.png)	22
2.12	Activity diagram of the process chain	27
2.13	Visualization of the Conversion Service	28
2.14	Visualization of the Annotation Service	29
2.15	Visualization of the Tessellation Service	29
3.1	Content of input directory	39
4.1	Example of context regions (B, C are context of A; A, C are context of B; A, B are context of C; D has no context region) . .	42
4.2	Microdraw GUI with opened WSI	45
4.3	Hello, World! example on how to use Flasks route() decorator (source: [30])	47
4.4	Example use of the method argument (source: [30])	48

List of Tables

2.1	File formats by vendor	9
2.2	Valid values for <i>region</i> parameter (source: [24])	14
2.3	Valid values for <i>size</i> parameter (source: [24])	16
3.1	File formats by vendor	31
3.2	Overview of conversion options for zooming image formats (source: [36])	32
3.3	Options for deepzoom.py	34
3.4	Options for VIPS	36
3.5	Results of Conversion Service Test	39
4.1	Parameters for as_server.py	46
4.2	Available converters in Flask (source: [30])	48
4.3	DeepZoomGenerator parameters (with default values, source: [53])	49
4.4	DeepZoomGenerators get_tile parameters (source: [53])	50
A.1	Aperio data set (source: http://openslide.cs.cmu.edu/download/openslide-testdata/Aperio/)	55
A.2	Generic Tiled tiff data set (source: http://openslide.cs.cmu.edu/download/openslide-testdata/Generic-TIFF/)	56
A.3	Hamamatsu data set (.ndpi, source: http://openslide.cs.cmu.edu/download/openslide-testdata/Hamamatsu/)	56
A.4	Hamamatsu data set (.vms, source: http://openslide.cs.cmu.edu/download/openslide-testdata/Hamamatsu-vms/)	56
A.5	Leica data set (source: http://openslide.cs.cmu.edu/download/openslide-testdata/Leica/)	57
A.6	Mirax data set (source: http://openslide.cs.cmu.edu/download/openslide-testdata/Mirax/)	58
A.7	Trestle data set (source: http://openslide.cs.cmu.edu/download/openslide-testdata/Trestle/)	59
A.8	Trestle data set (source: http://openslide.cs.cmu.edu/download/openslide-testdata/Trestle/)	59

Nomenclature

AS	Annotation Service
ASV	Annotation Service Viewer
BNN	Biological Neural Networks
CS	Conversion Service
DICOM	Digital Imaging and Communications in Medicine
DZI	Deep Zoom Image
DZI	Deep Zoom Images
GUI	Graphical User Interface
GUI	Graphical User Interface
MS	Microservice
NN	Neural Network
NN	Neural Networks
TS	Tessellation Service
VIPS	VASARI Image Processing System
WSI	Whole Slide Image
